

HOTEL MANAGEMENT SYSTEM

Problem Statement

Managing hotel information manually can become difficult when the number of rooms and customers increases. Maintaining customer details in notebooks or separate files makes searching and updating information less convenient.

The problem addressed by this project is to create a simple computer-based system where basic hotel information can be stored and displayed through a web interface. The system provides a simple way to view hotel rooms, display room type, price and availability, register customer information, store customer details in a database, and access the information through a web browser.

Main Problems Addressed

No.	Problem
1	Manual maintenance of hotel and customer information can be time-consuming.
2	Customer details stored separately can be difficult to search and update.
3	Room information and availability need to be displayed in an organized manner.
4	Customer information needs to be stored in a database.
5	A simple web interface is needed to access the basic information easily.

Project Focus: The current implementation is a basic academic Hotel Management System developed using Python and Flask, with SQLite used for data storage. It mainly focuses on room information and customer registration.
